Summary

The results of doxophilline efficacy and safety study administered for 1 month in patients with stage 3 COPD have been presented. It was revealed that in COPD patients doxophilline was more effective in terms of improvement of physical exercise tolerance and functional capacity — decreased lung hyperinflation, increased bronchial passage, reduced dyspnea. Doxophilline produced meaningful anti-inflammatory effect, improving NST-test parameters in group 1 of patients. Doxophilline was better tolerated, causing no adverse events.
